WPI Acc no: 1999-010190/199901

Related WPI Acc No: 1998-033010; 1998-042509; 1999-106398

XRFX Acc No: N1999-007470

Subscriber unit for multiple speed channel communications - has number of input sources mapped and Walsh code converted before being spread coded and quadrature modulated for output

Patent Assignee: ODENWALDER J P (ODEN-I); QUALCOMM INC (QUAL-N)

Inventor: ODENWALDER J P; ODENWALDER J

Patent Family (36 patents, 81 countries)

Alerting Abstract WO A2

The cellular communications system provides subscriber communications using a number of information sources per subscriber, e.g. voice, video. A pilot signal (402), control channel (415) and two information channels are combined into one transmission. The first information channel (404) is mapped (405) and subjected to four symbol Walsh coding (Wf). The second information channel is also mapped (412) and Walsh coded using a two symbol code (Ws). An eight symbol Walsh code is used on the control data. The sources are amplified, spread coded and quadrature modulated with the pilot signal for transmission. ADVANTAGE - Using Walsh codes of different lengths gives different data rates of high capacity and efficiency.

Title Terms /Index Terms/Additional Words: SUBSCRIBER; UNIT; MULTIPLE; SPEED; CHANNEL; COMMUNICATE; NUMBER; INPUT; SOURCE; MAP; WALSH; CODE; CONVERT; SPREAD; QUADRATURE; MODULATE; OUTPUT

Original Abstract: The invention relates to a method and a transmitter apparatus for a variable data rate signal. The invention provides an interleaver configured to interleave a frame of code symbols to produce a sequence of interleaved symbols having a first predetermined number of symbols. A repeater is configured to repeat the sequence of interleaved symbols a number of times and to repeat a subset of the sequence of interleaved symbols, wherein the subset has a second predetermined number of symbols, and wherein the second predetermined number of symbols is less than the first predetermined number of symbols.

Claim:

1. A method of transmitting a variable data rate signal comprising:

- interleaving a frame of code symbols to produce a sequence of interleaved symbols having a first predetermined number of symbols;
- repeating the sequence of interleaved symbols a number of times; and

- repeating a subset of the sequence of interleaved symbols, wherein the subset has a second predetermined number of symbols, and wherein the second predetermined number of symbols is less than the first predetermined number of symbols.

Original Abstract: A set of individually gain adjusted subscriber channels (402, 404, 411, 415) are formed via the use of a set of orthogonal subchannel codes (W_c , W_s , W_f) having a small number of PN spreading chips per orthogonal waveform period. Data to be transmitted via one of the transmit channels is low code rate error correction encoded and sequence repeated before being modulated with one of the subchannel codes, gain adjusted, and summed with data modulated using the other subchannel codes. The resulting summed data (410, 420) is modulated using a user long code and a pseudorandom spreading code (PN code) and upconverted for transmission. The use of the short orthogonal codes provides interference suppression while still allowing extensive error correction coding and repetition for time diversity to overcome the Raleigh fading commonly experienced in terrestrial wireless systems. The set of sub-channel codes may comprise four Walsh codes, each orthogonal to the remaining codes of the set. The use of four sub-channels is preferred as it allows shorter orthogonal codes to be used, however, the use of a greater number of channels and therefore longer codes is acceptable. Preferably, pilot data is transmitted via a first one of the transmit channels and power control data transmitted via a second transmit channel. The length, or number of chips, in each channel code may be different to further reduce the peak-to-average transmit power for higher rate data transmission.

Claim:

- I. Ein Verfahren zum Modulieren eines Signals durch Erzeugen von Daten zur Übertragung, und zwar geeignet zu Übertragung von einer Teilnehmereinheit zu einer Basisstation, in einem Kommunikationssystem bzw. Nachrichtenermittlungssystem **gekennzeichnet dadurch, dass** das Verfahren die folgenden Schritte aufweist:
 - Modulieren von kanalcodierten Daten von einer Vielzahl von Kanälen mit einem assoziierten Code für jeden Kanal, ausgewählt aus einer Anzahl von assoziierten Codes, wobei jeder assoziierte Code eine unterschiedliche Länge von verbleibenden assoziierten Codes besitzt und jeder assoziierte Code orthogonal zu verbleibenden assoziierten Codes ist, und zwar zum Erzeugen einer Vielzahl von Strömen mit modulierten Symbolen;
 - Kombinieren der Vielzahl von Strömen mit modulierten Symbolen in zwei kombinierte Ströme; und
 - komplexes Multiplizieren der zwei kombinierten Ströme mit einem komplexen Pseudo-Rausch-Code.
- I. A method for modulating a signal by generating data for transmission suitable for transmission from a subscriber unit to a base station in a communication system **characterised in that** the method comprises the steps of:
 - modulating channel encoded data from a plurality of channels with an associated code for each channel, selected from a number of associated codes, wherein each associated code is of a different length from remaining associated codes and each associated code is orthogonal to remaining associated codes, to produce a plurality of streams of modulated symbols;
 - combining the plurality of streams of modulated symbols into two combined streams; and
 - complex multiplying said two combined streams with a complex pseudonoise code.
- I. Procédé de modulation d'un signal en produisant des données pour transmission adaptées à une transmission d'un poste d'abonné à une station de base dans un système de communication, **caractérise en ce que** le procédé comprend les étapes suivantes:

- moduler des données codées de canal en provenance d'une pluralité de canaux par un code associé pour chaque canal, choisi parmi plusieurs codes associés, dans lequel chaque code associé a une longueur différente des autres codes associés et chaque code associé est orthogonal aux autres codes associés, pour produire une pluralité de flux de symboles modules;
- combiner la pluralité de flux de symboles modules en deux flux combinés; et
- effectuer une multiplication complexe des deux flux combinés par un code complexe de pseudobruit.

Original US Class (secondary): 375149 375148

Original Abstract: A method and apparatus for high rate CDMA wireless communication is described. A set of individually gain adjusted subscriber channels are formed via the use of a set of orthogonal subchannel codes having a small number of PN spreading chips per orthogonal waveform period. Data to be transmitted via one of the transmit channels is low code rate error correction encoded and sequence repeated before being modulated with one of the subchannel codes, gain adjusted, and summed with data modulated using the other subchannel codes. The resulting summed data is modulated using a user long code and a pseudorandom spreading code (PN code) and upconverted for transmission. The use of the short orthogonal codes provides interference suppression while still allowing extensive error correction coding and repetition for time diversity to overcome the Raleigh fading commonly experienced in terrestrial wireless systems.

Claim: What is claimed is:

1. 1. An method for demodulating a signal comprising:

- multiplying an in-phase sample stream by a first short Walsh cover having a duration of fewer than sixty-four chips per orthogonal waveform period to produce an in-phase short Walsh despread symbol first channel stream;
- multiplying a quadrature-phase sample stream by the first short Walsh cover to produce a quadrature-phase short Walsh despread symbol first channel stream; and
- adding the in-phase short Walsh despread symbol first channel stream to the quadrature-phase short Walsh despread symbol first channel stream to produce a soft decision first channel data stream.

Original Abstract: Method and apparatus for high rate code-division multiple access wireless communication is described. Each of a channel encoded data is modulated by an associated code having a small number of pseudo-noise spreading chips per orthogonal waveform period, thus producing a set of streams of modulated symbols. Each of the set of streams of modulated symbols is then gain adjusted, and combined to yield two streams of combined symbols. The combination is the set of streams is carried out to reduce a peak-to-average ratio of the transmission. The resulting two combined symbol streams are modulated by a complex multiplier using a user long code and a pseudorandom spreading code (PN code) and upconverted for transmission.

Claim: I (We) claim:

I. 1. A method for generating data for transmission from a subscriber unit to a base station, the method comprising:

- modulating each of a plurality of channel encoded data with an associated code to produce a plurality of streams of modulated symbols;

- combining the plurality of streams of modulated symbols into two combined streams to reduce a peak-to-average ratio of the transmission; and
- complex multiplying said two combined streams with a complex pseudonoise code.

Original Abstract: A method and apparatus for high rate CDMA wireless communication is described.

Variable data rates are generated using a set of different encoder, interleaver, and symbol repetition configurations. An encoder associated with each rate generates a variable number of symbols during each frame period. This variable number of symbols is repeated as necessary to form a constant number of symbols equal to a fixed number of symbols that can be then repeated a fixed number of repetitions before transmission. Where the constant number of symbols is not an integer multiple of the variable number of symbols for a particular rate, a subset of the variable number of symbols is repeated to fill in the remaining symbols necessary to equal the constant number of symbols.

Claim: What is claimed is:

1. 12. A transmitter apparatus comprising:

- an interleaver configured to interleave a frame of code symbols to produce a sequence of interleaved symbols having a first predetermined number of symbols; and
- a repeater configured to repeat the sequence of interleaved symbols a number of times and to repeat a subset of the sequence of interleaved symbols, wherein the subset has a second predetermined number of symbols, and wherein the second predetermined number of symbols is less than the first predetermined number of symbols.

Original Abstract: A method and apparatus for demodulation in high rate CDMA wireless communication is described. In a described high rate CDMA wireless system, a transmitter forms a set of individually gain adjusted subscriber channels using a set of orthogonal subchannel codes having a small number of PN spreading chips per orthogonal waveform period. An illustrative high rate CDMA wireless system uses Walsh codes, each having a duration of fewer than sixty-four chips per orthogonal waveform period. A receiver demodulates each of the subscriber channels using the same orthogonal subchannel codes.

Claim: What is claimed is:

I. 25. A receiver apparatus comprising:

- means for complex-multiplying a complex received signal by an in-phase pseudorandom spreading code and a quadrature-phase pseudorandom spreading code to provide an in-phase sample stream and a quadrature-phase sample stream;
- means for filtering the in-phase sample stream to provide an in-phase pilot filter signal;
- means for filtering the quadrature-phase sample stream to provide a quadrature-phase pilot filter signal;
- means for multiplying the in-phase sample stream by a first short Walsh cover having a duration of fewer than sixty-four chips per orthogonal waveform period to produce an in-phase short Walsh despread symbol first channel stream;
- means for multiplying the quadrature-phase sample stream by the first short Walsh cover to produce a quadrature-phase short Walsh despread symbol first channel stream; and
- means for phase rotating and scaling the quadrature-phase short Walsh despread symbol first channel stream and the in-phase short Walsh despread symbol first channel stream based on the in-phase pilot filter signal and the quadrature-phase pilot filter signal to produce a soft decision first channel data stream.

Original Abstract: A set of individually gain adjusted subscriber channels (402, 404, 411, 415) are formed via the use of a set of orthogonal subchannel codes (W_c , W_s , W_f) having a small number of PN spreading chips per orthogonal waveform period. Data to be transmitted via one of the transmit channels is low code rate error correction encoded and sequence repeated before being modulated with one of the subchannel codes, gain adjusted, and summed with data modulated using the other subchannel codes. The resulting summed data (410, 420) is modulated using a user long code and a pseudorandom spreading code (PN code) and upconverted for transmission. The use of the short orthogonal codes provides interference suppression while still allowing extensive error correction coding and repetition for time diversity to overcome the Raleigh fading commonly experienced in terrestrial wireless systems. The set of sub-channel codes may comprise four Walsh codes, each orthogonal to the remaining codes of the set. The use of four sub-channels is preferred as it allows shorter orthogonal codes to be used, however, the use of a greater number of channels and therefore longer codes is acceptable. Preferably, pilot data is transmitted via a first one of the transmit channels and power control data transmitted via a second transmit channel. The length, or number of chips, in each channel code may be different to further reduce the peak-to-average transmit power for higher rate data transmission.
